How to use CLion as Front-End for TRACE32?

2026-08-03 - Comments (0) - TRACE32 PowerView

Getting Started with TRACE32 in CLion

This guide explains how to configure **JetBrains CLion** to use **TRACE32** as the debugger through the **TRACE32 Debug Adapter (DAP)**.

Once configured, you can start, stop, step through code, inspect variables, and debug your target directly from within CLion while TRACE32 handles all communication with the target hardware.

Prerequisites

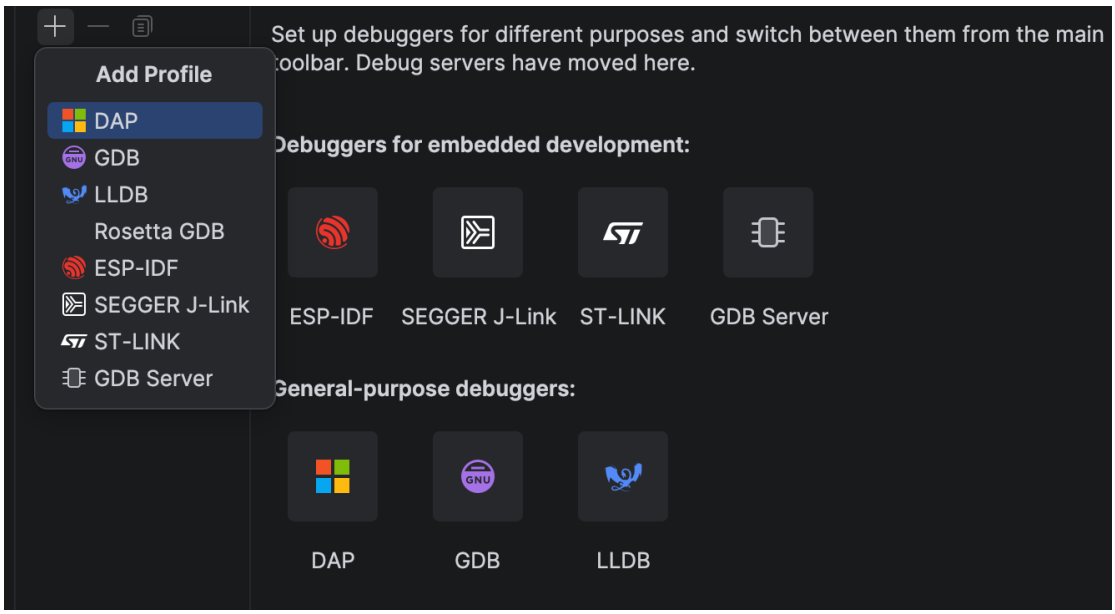
Before you begin, make sure you have the following installed:

- JetBrains CLion with Debug Adapter Protocol (DAP) support (minimum version 2026.1)
- TRACE32 PowerView, minimum build number 192017 or Release 09.2026
- TRACE32 Debug Adapter (`t32debugadapter`) (min: version 0.0.30)
- A working TRACE32 configuration for your target
- An application built with debug information

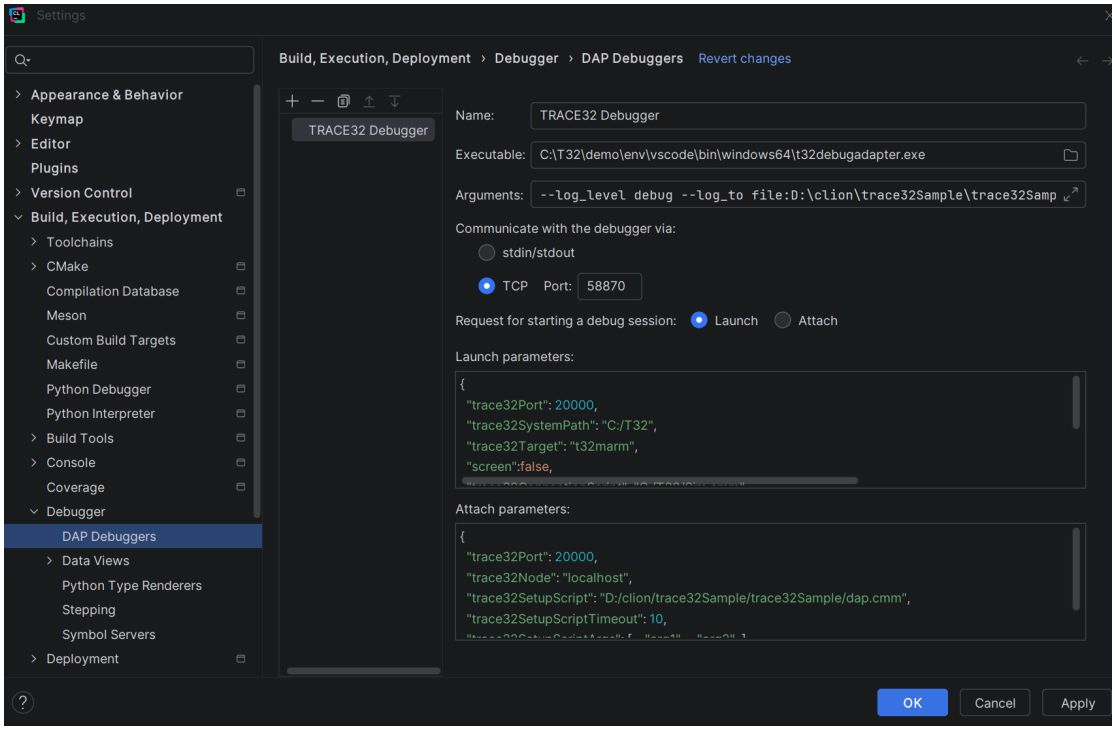
It is recommended to verify that TRACE32 can connect to your target before configuring CLion.

Step 1 – Configure the TRACE32 Debug Adapter

Open the CLion settings, Go to **Build, Execution, Deployment > Debugger > DAP Debuggers** and then click **+** to add a new DAP debugger.



Configure the debugger as follows:



Example for Launch parameters:

```
{
  "trace32Port": 20000, // API port used to communicate with TRACE32.
  "trace32SystemPath": "C:/T32", // Path to the TRACE32 installation.
  "trace32Target": "t32marm", // Name of the TRACE32 executable to launch.
  "screen": false, // Optional. If set to false, TRACE32 PowerView runs in the
background.
  "trace32ConnectionScript": "C:/T32/ConnectionScript.cmm", // Script used to
configure and launch TRACE32.
  "trace32SetupScript": "D:/clion/trace32Sample/trace32Sample/dap.cmm", // Script that
connects to the target CPU and loads the application.
  "trace32SetupScriptTimeout": 10, // Optional. Timeout in seconds to wait for the
setup script to complete.
  "trace32SetupScriptArgs": [
    "arg1",
```

```
    "arg2"
  ] // Optional. Arguments passed to the setup script.
}
```

These parameters allow the Debug Adapter to launch TRACE32 and initialize the debugging session automatically.

Example for Attach parameters:

```
{
  "{
  "trace32Port": 20000, // Optional. API port used to communicate with TRACE32.
Defaults to 20000 if not specified.
  "trace32SetupScript": "D:/clion/trace32Sample/trace32Sample/dap.cmm", // Optional.
Script executed after TRACE32 is launched. Typically used to connect to the target CPU
and load the application.
  "trace32SetupScriptTimeout": 10, // Optional. Timeout, in seconds, to wait for the
setup script to complete.
  "trace32SetupScriptArgs": [
    "arg1",
    "arg2"
  ] // Optional. Arguments passed to the setup script.
}
```

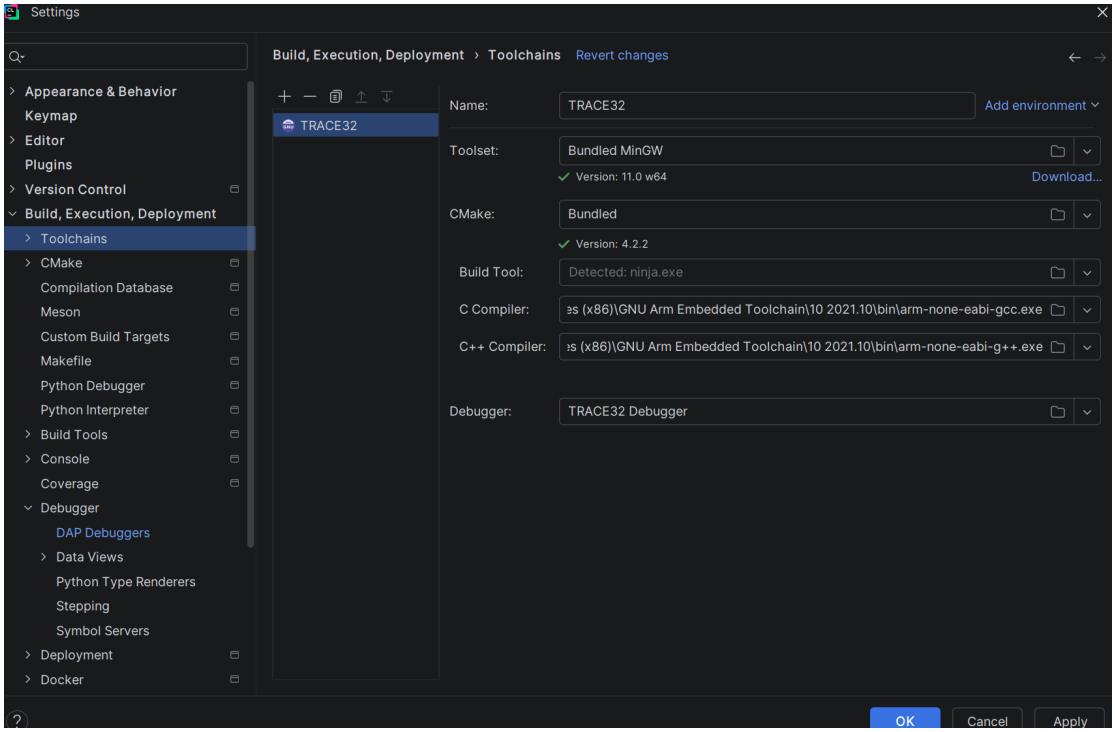
These parameters allow the Debug Adapter to connect to a running TRACE32 PowerView and, optionally, initialize the debugging session using the trace32SetupScript.

Click **Apply** then **OK**.

Step 2 – Configure the Toolchain

1. Go to **Settings > Build, Execution, Deployment > Toolchains** and select your toolchain.

2. Select the **TRACE32** debugger created in the previous step from the **Debugger** drop-down list and click **OK**.



Step 3 – Create a Debug Configuration

1. Open **Run → Edit Configurations...**.
2. Click **+** and select the appropriate configuration type for your project (for example, **CMake Application** for CMake-based projects).
3. Configure the following settings:
    - **Name** – A descriptive name for the configuration.
    - **Executable/Target** – Select the executable to debug.

Save the configuration.

Step 4 – Start a Debug Session

Click **Debug** in CLion.

The following sequence is performed automatically:

1. CLion starts the TRACE32 Debug Adapter.
2. The Debug Adapter launches TRACE32 PowerView.
3. TRACE32 PowerView executes the connection script.
4. TRACE32 PowerView executes the startup script.
5. The application is loaded.
6. Control is returned to CLion.

You can now debug your application directly from the IDE.

Ending the Debug Session

When debugging is complete:

1. Click **Stop** in CLion.
2. The Debug Adapter terminates the DAP session.
3. TRACE32 PowerView is closed or disconnected, depending on the adapter configuration.

Troubleshooting

TRACE32 does not start

Verify that:

- `t32debugadapter.exe` exists.
- The executable path is correct.
- The TRACE32 installation directory is valid.

TRACE32 cannot connect to the target

Verify that:

- The connection script is correct.
- The target hardware is powered.
- TRACE32 can connect successfully when started manually.

The application is not loaded

Verify that:

- The ELF file exists.
- The startup script loads the correct ELF file.
